The following figures display for each of our program stars the observed spectrum (blue) with a model (red). The upper panel, corresponding to Fig. 3, shows the spectral energy distribution (IUE low-resolution spectrum if available, visual and 2MASS photometry). The model SED was geometrically diluted according to the distance modulus *DM* and reddened with E_{b-v} as given in the figure. Keywords or indicate the applied reddening law (default: Seaton's law), the given parameter being R_V (see Sect. 4.2).

Most models were taken from our PoWR model grids (see Hamann & Gräfener 2004). The grid parameters are $\log T_*$ and $\log R_t$. Note that the grids were calculated for a fixed luminosity of $\log L/L_\odot$ = 5.3, and only scaled for the individual star; the scaling factor is indicated as the logarithmic "shift" in the plots. The so-called WNE grid is calculated for zero hydrogen and a terminal wind velocity of 1600 km/s, while the models in the WNL grid have 20% hydrogen (by mass) and v_∞ = 1000 km/s.

As the plotted models are mostly taken from the prepared grids (if not otherwise stated), their hydrogen abundance $X_{\rm H}$ and terminal velocity v_∞ do generally not agree precisely with the final parameters of our analysis as given in Table 2.

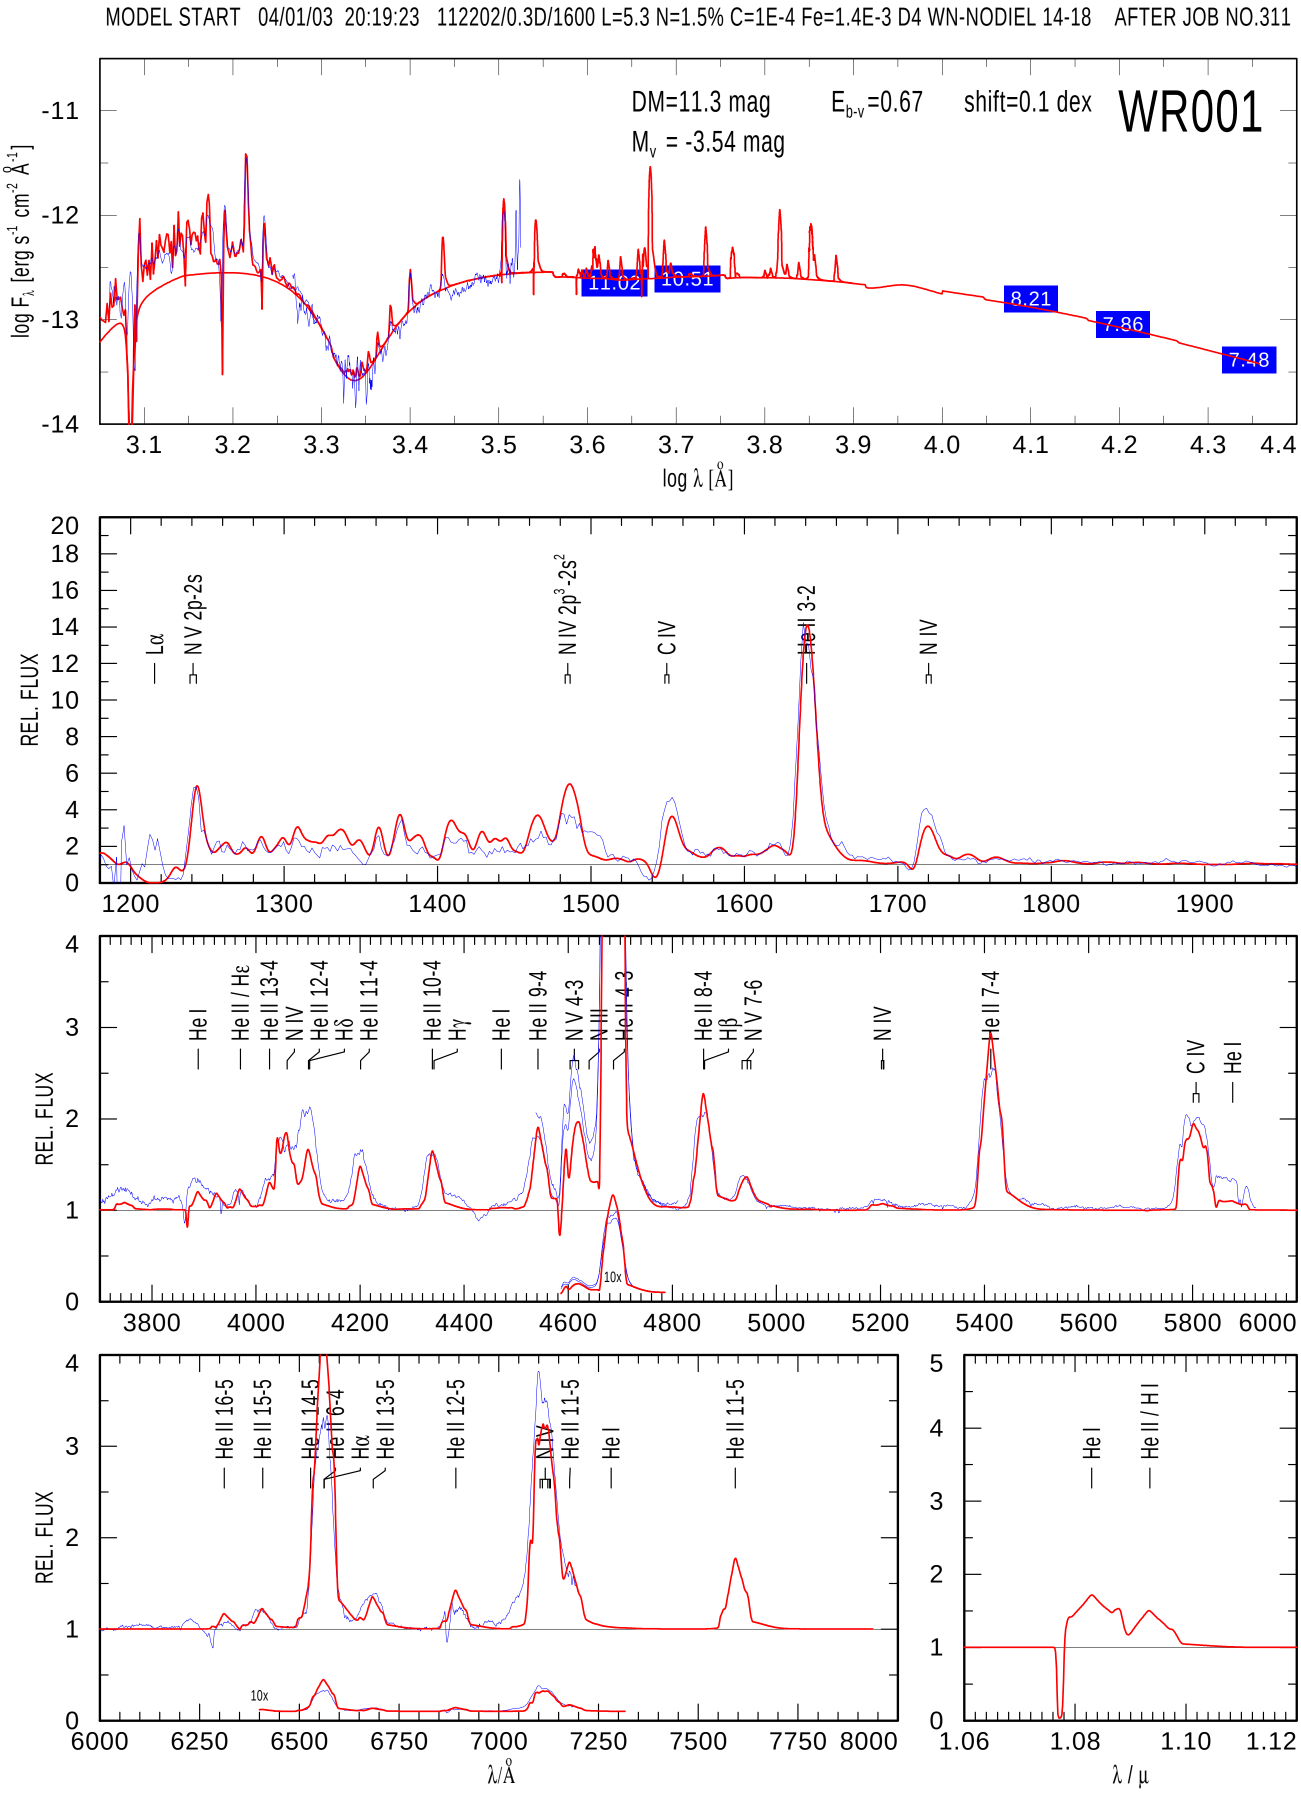

Fig. 12. Model: WNE 14-18, $T_* = 112\,\mathrm{kK}$, $\log(R_t/R_\odot) = 0.3$

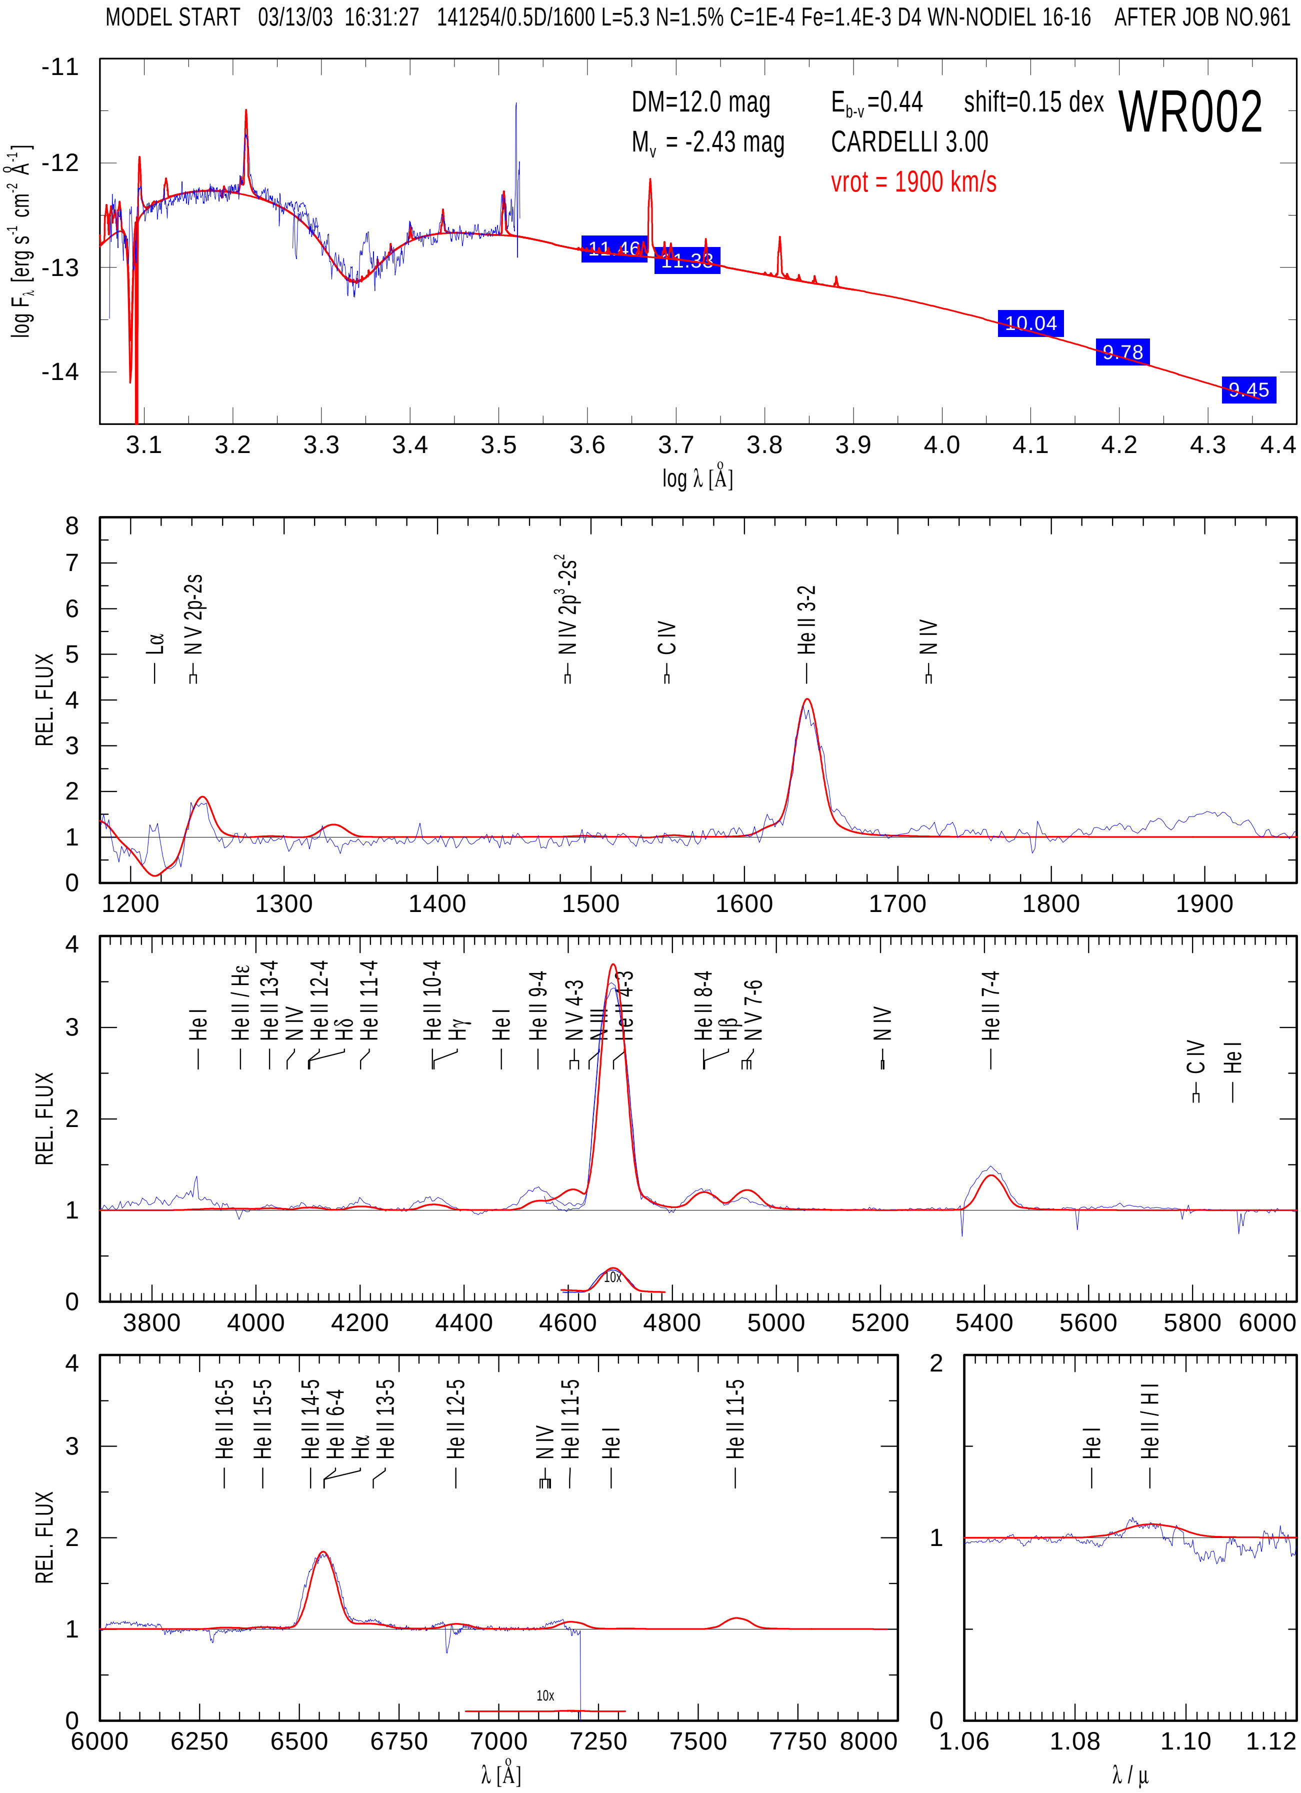

Fig. 13. Model: WNE 16-16, $T_* = 141$ kK, $\log(R_t/R_\odot) = 0.5$

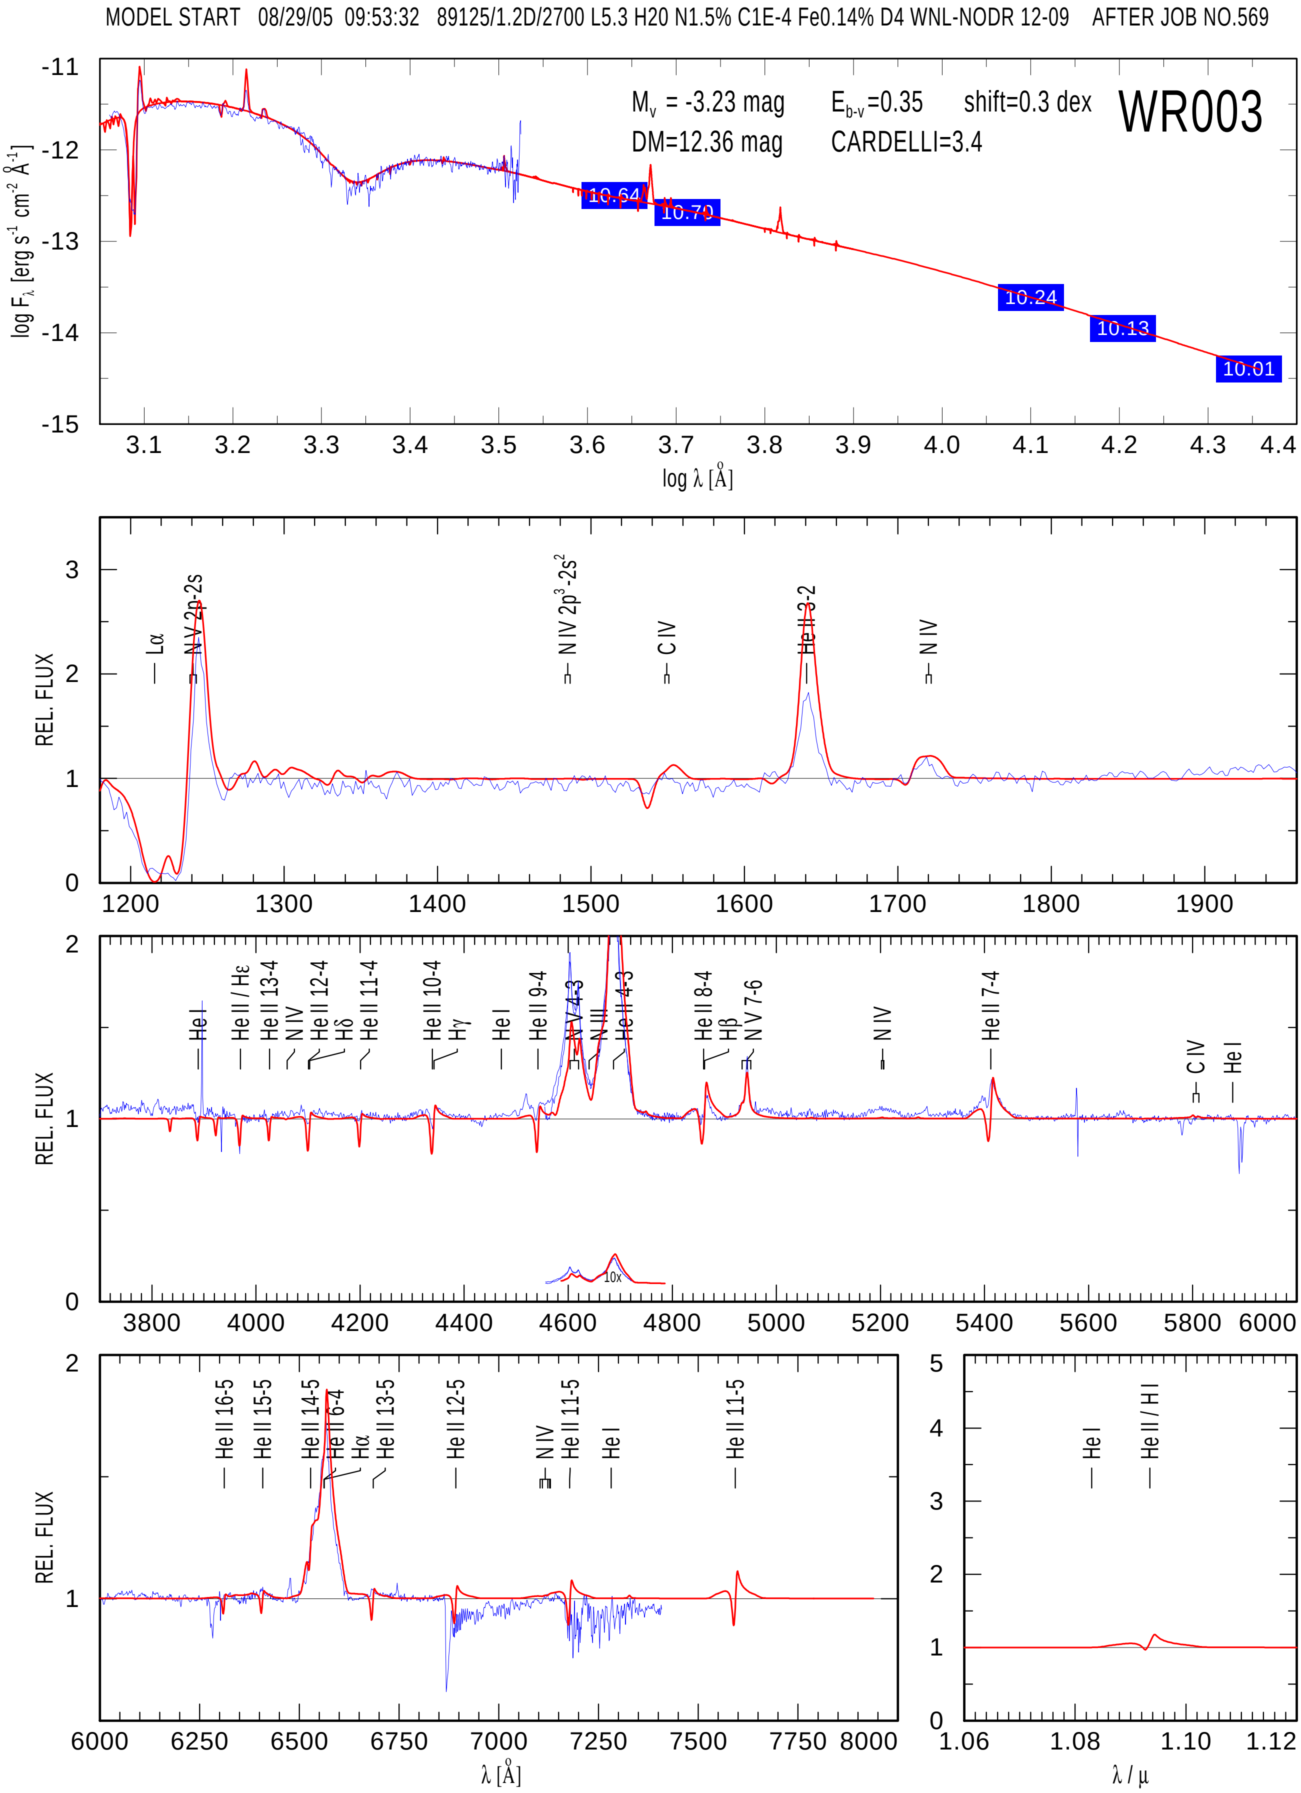

Fig. 14. Individual Model: WNL 12-09, $T_* = 89$ kK, $\log(R_t/R_\odot) = 1.2$ but $v_\infty = 2700$ km/s

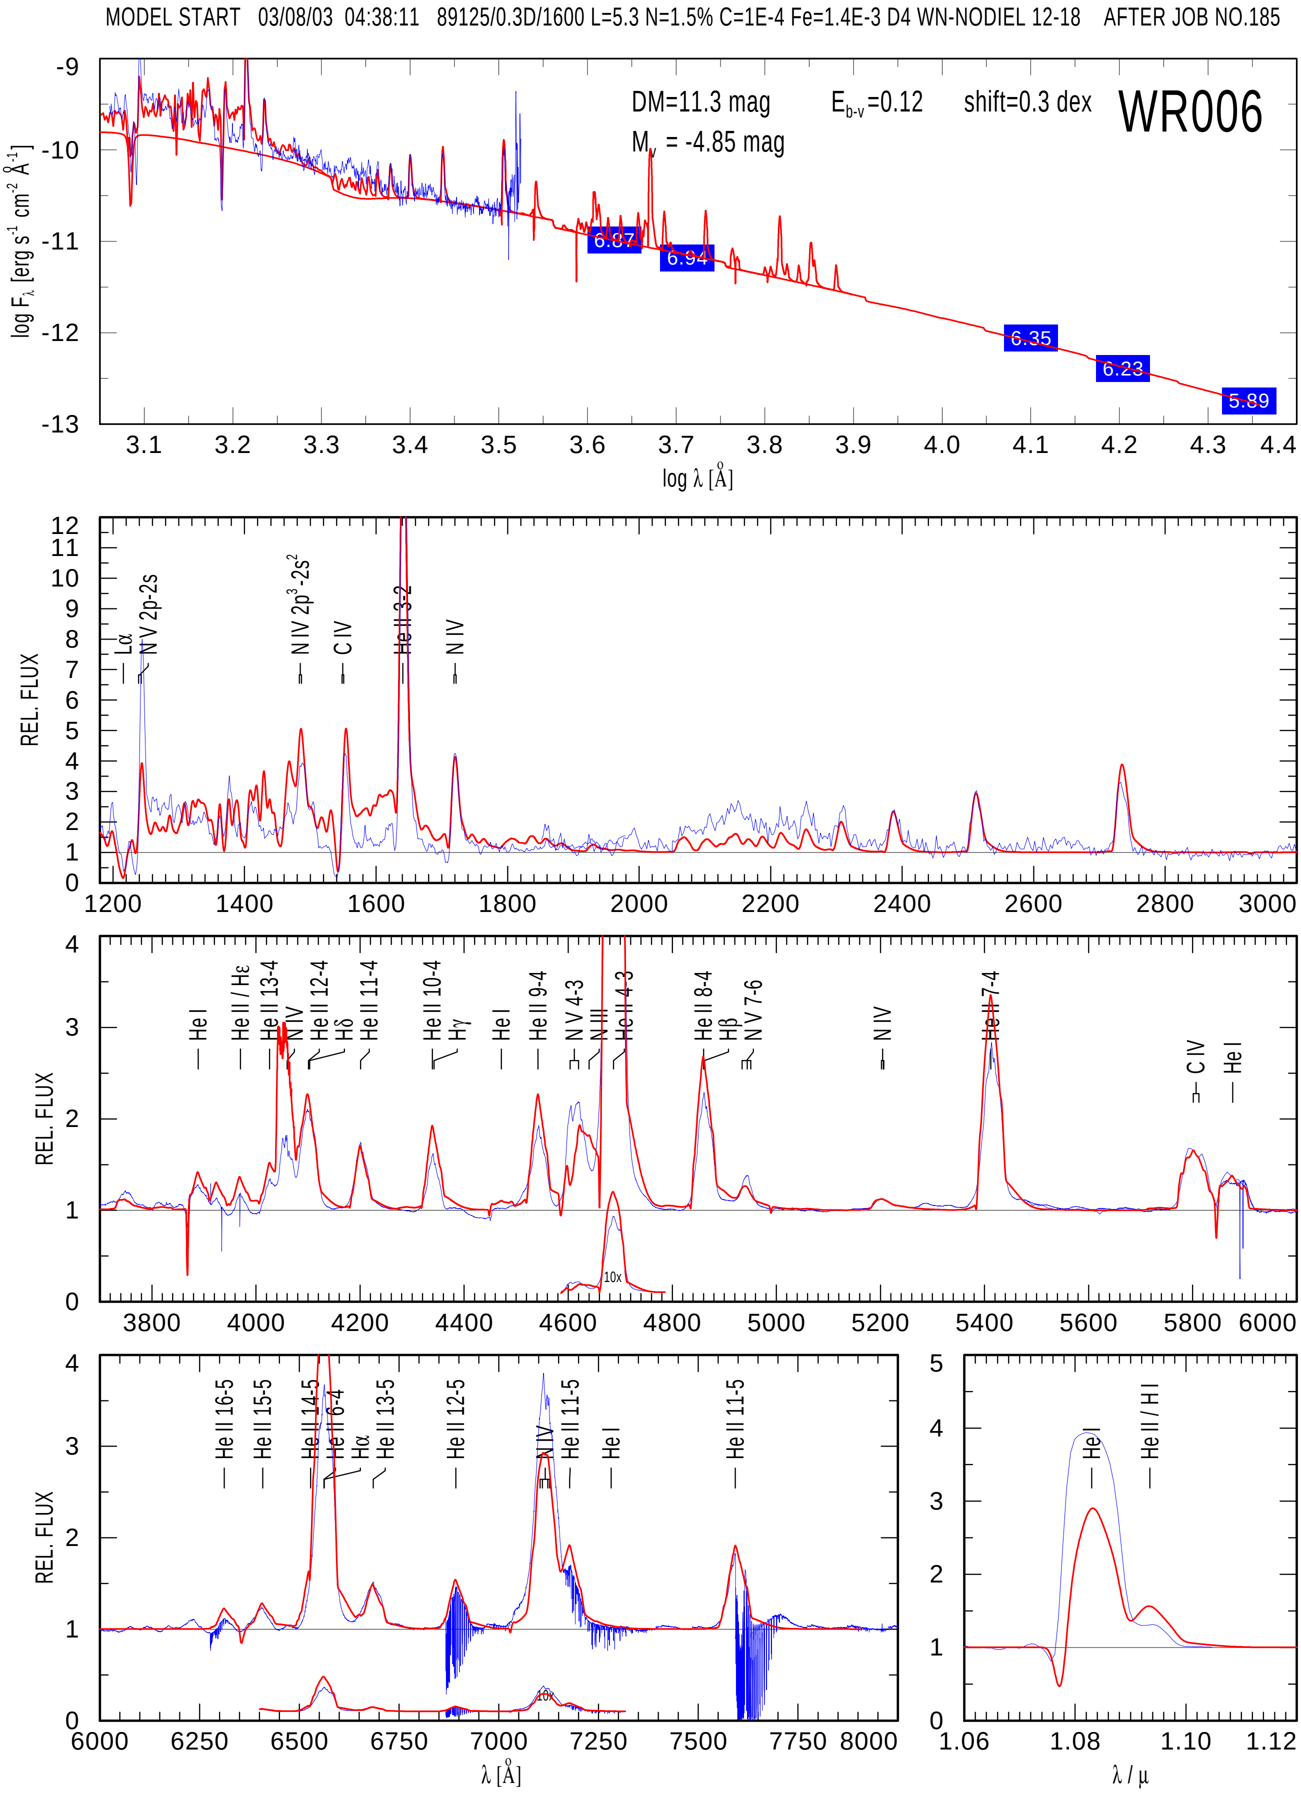

Fig. 15. Model: WNE 12-18, $T_* = 89$ kK, $\log(R_t/R_\odot) = 0.3$
